

Surface Measurements (Las mediciones de superficie) 24 Hour PM_{2.5} Samples in Santiago (Sep 22/23/24, 2013)

Measurements from the Parque O'Higgins Station. Plot from Sistema Nacional de Calidad del Aire Web Site (<http://sinca.mma.gob.cl>)

Atmospheric Transport

Forces in the Atmosphere:

- Gravity g
- Pressure-gradient $\gamma_p = - (1/\rho) \nabla' P$
- Coriolis $\gamma_c = 2\omega v \sin \lambda \rightarrow$ To **Right** of direction of motion in **Northern Hemisphere** and to **Left** in **Southern Hemisphere**
- Friction $\gamma_f = -kv$

ρ - Density

P - Pressure

ω - Angular Velocity of the Earth

V - Speed of Object

Equilibrium of Forces:

In vertical: barometric law

In horizontal: *geostrophic* flow parallel to isobars

In horizontal, near surface: flow tilted to region of low pressure

Courtesy of Daniel J. Jacob

Weather

Air converges near the surface in low pressure centers, due to the modification of geostrophic flow under the influence of friction. Air diverges from high pressure centers. At altitude, the flows are reversed: divergence and convergence are associated with lows and highs respectively.

The Hadley Circulation: Global Sea Breeze

Explains:

- Intertropical Convergence Zone (ITCZ)
- Wet tropics, dry poles
- Easterly trade winds in the tropics

But... Meridional transport of air between Equator and poles results in strong winds in the longitudinal direction because of conservation of angular momentum; this results eventually in unstable conditions.

Tropical Hadley Cell

- Easterly “trade winds” in the tropics at low altitudes
- Subtropical anticyclones at about 30° latitude

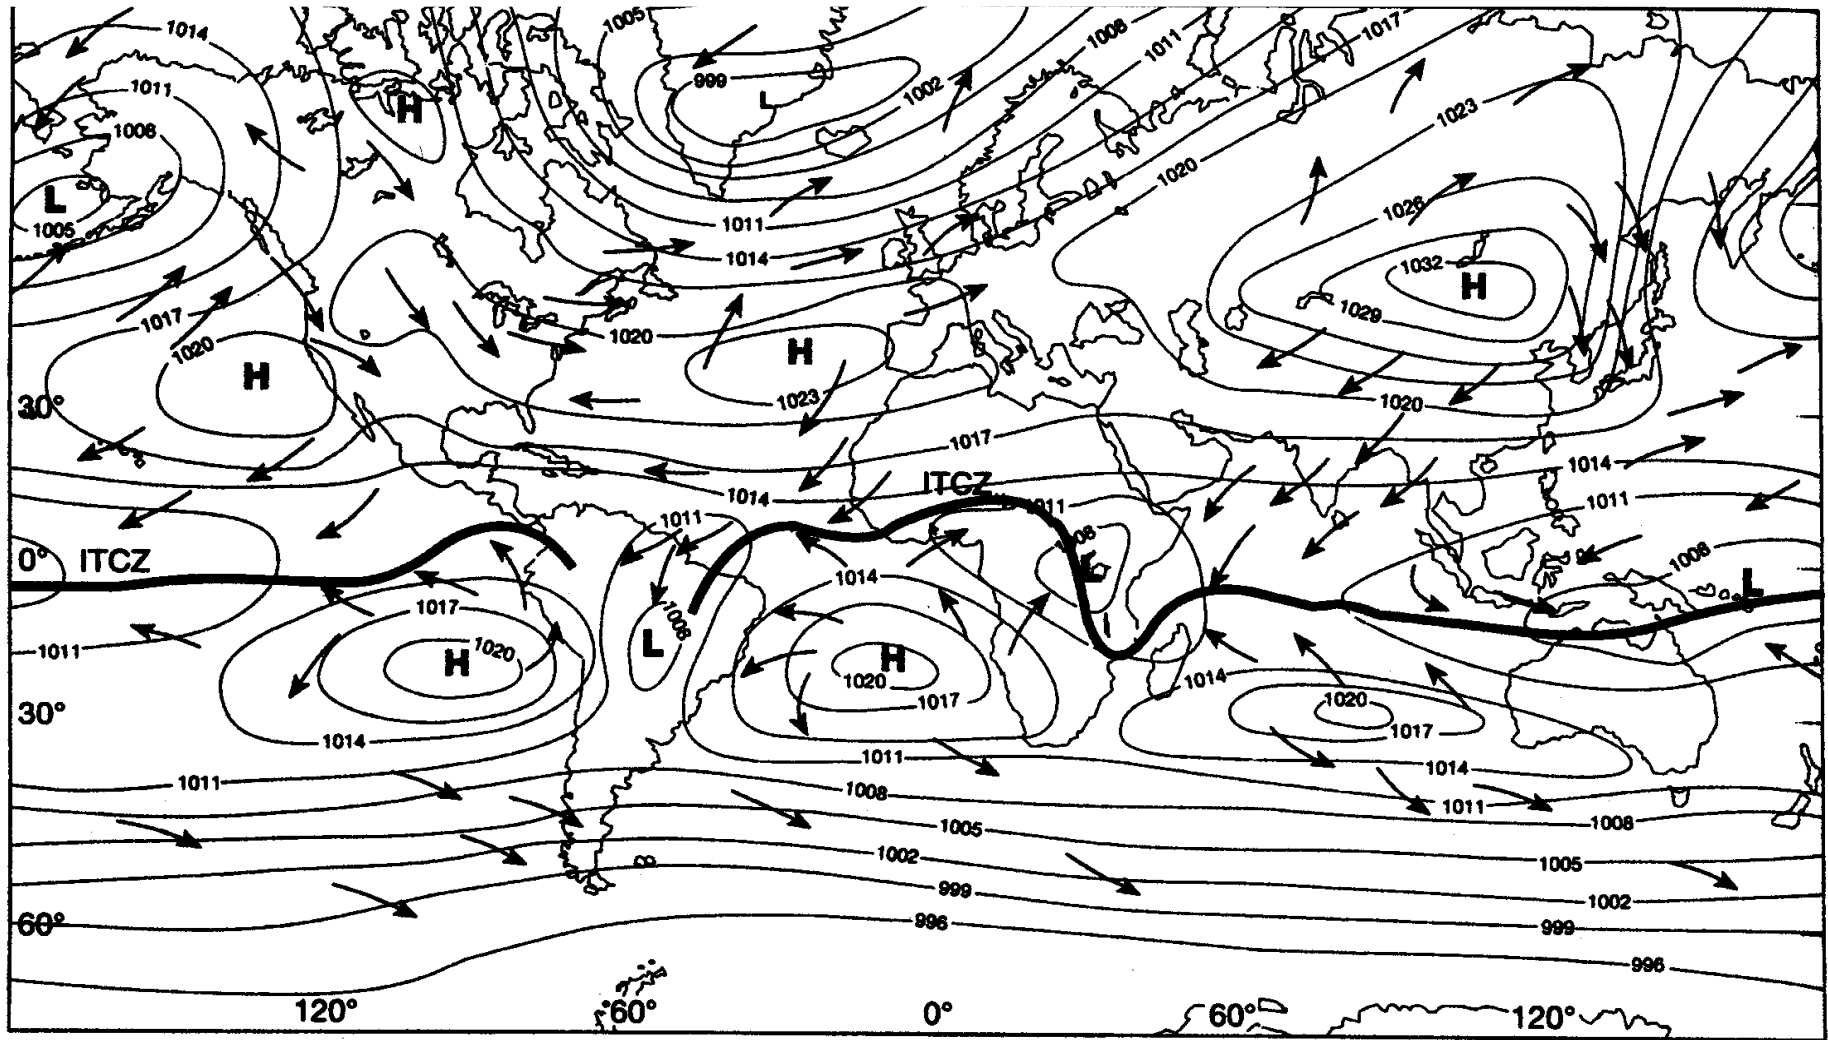

Fig. 4-11 Northern Hemisphere Hadley Cell.

Sea Level Pressure

Daily Maximum 8-h Average Ozone

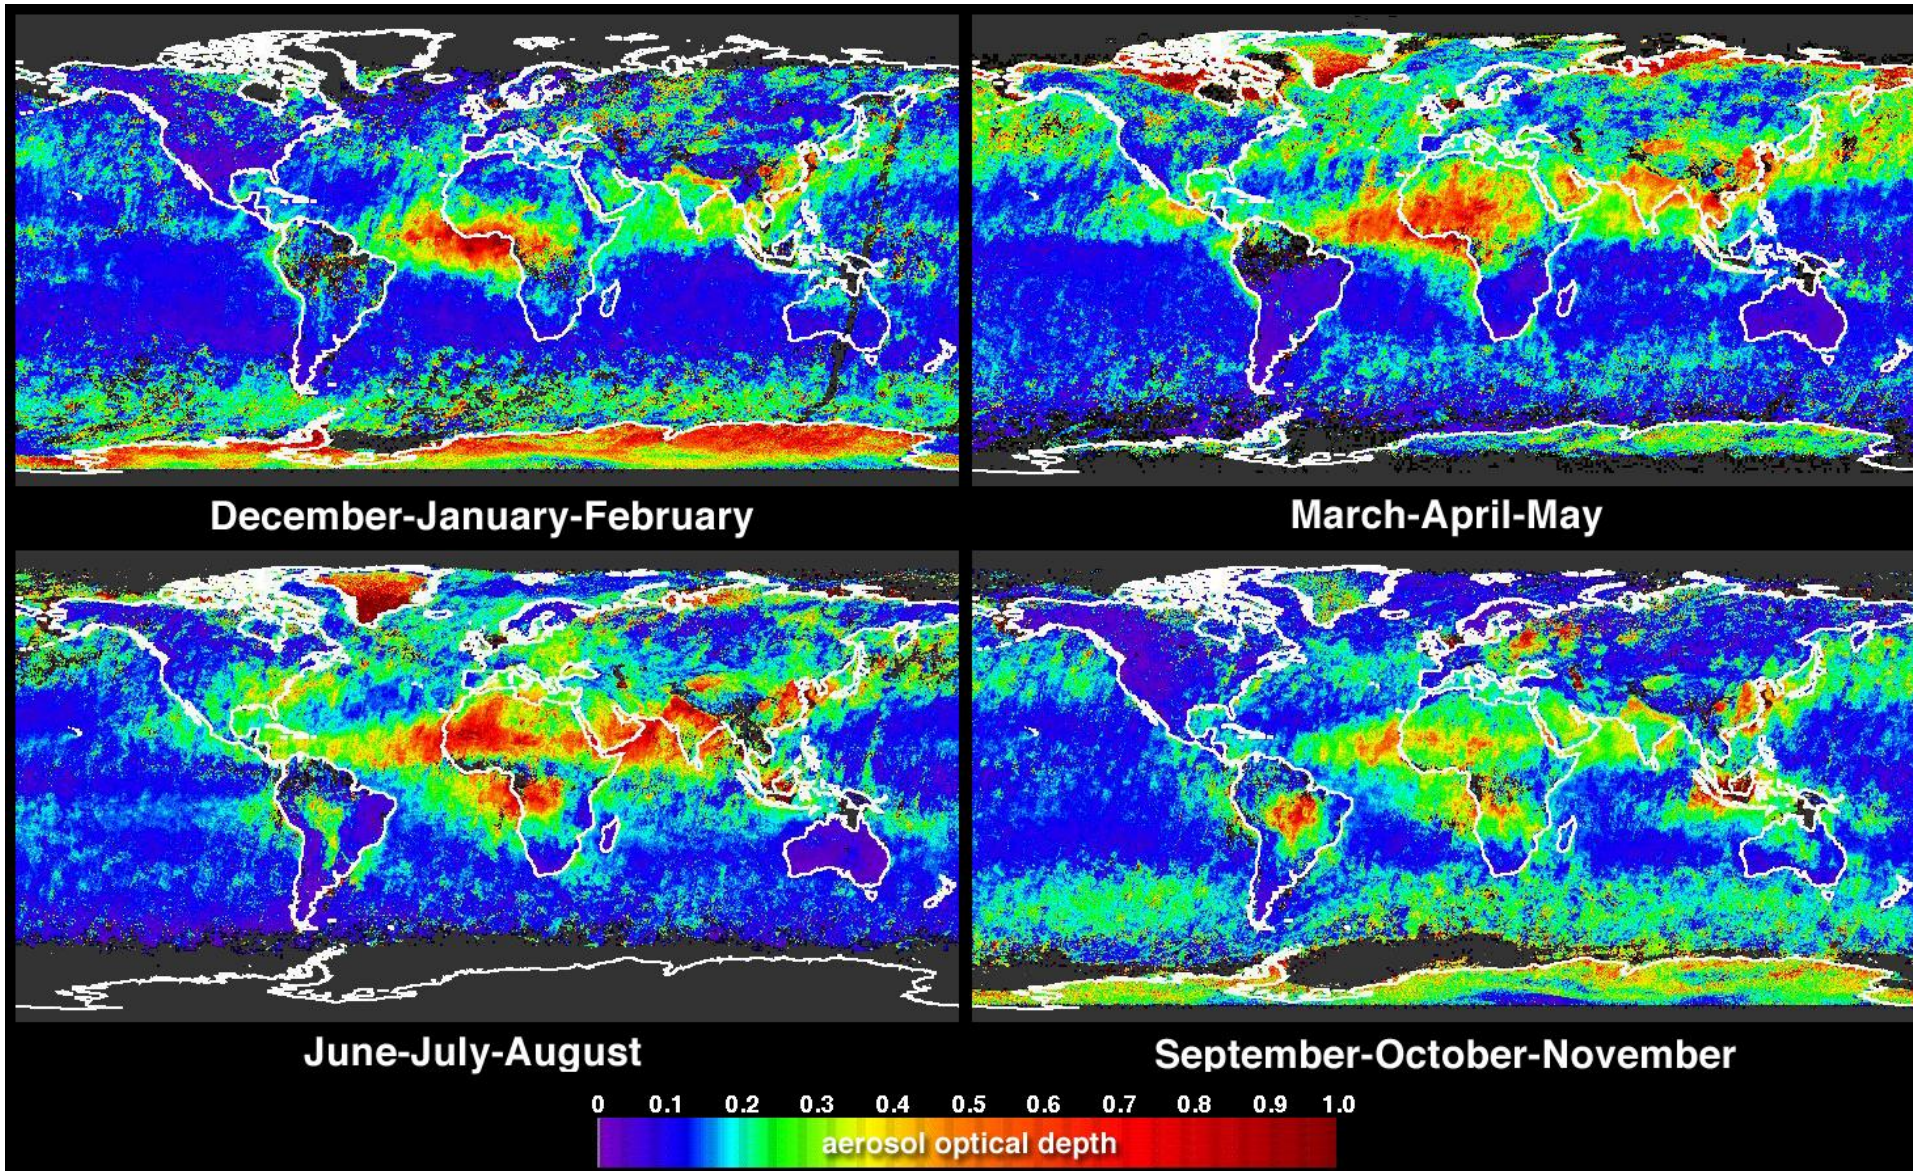

- **Cold fronts associated with cyclones tracking across southern Canada are the principal ventilation mechanism for the eastern US**
- **The frequency of these cyclones has decreased in past 50 years, likely due to greenhouse warming**

Vertical Transport: Buoyancy

Consider an object (density ρ) immersed in a fluid (density ρ'):

$$P(z) > P(z+\Delta z)$$

Therefore, pressure-gradient force (Y_b) on object directed upward

Buoyancy Acceleration (upward) : $Y_b = Y_p - g = \frac{\rho' - \rho}{\rho} g$

For air, $\rho = \frac{M_a P}{RT}$ so $\rho \uparrow$ as $T \downarrow$ Remember $p \sim 1/T$ (Ideal Gas Law)

Barometric law assumes $T = T'$ therefore $Y_b = 0$ (zero buoyancy)

T – Temperature of Object

T' – Temperature of fluid

$T \neq T'$ produces buoyant acceleration upward or downward

Optical Turbulence
(Thermosonde)

Helium Balloon

If a object (for example, Helium filled balloon connected to instrument package) is lighter than the fluid in which it is immersed, it is accelerated upward (see [video](#)).

CCN counter balloon package shortly after launch at Laramie, Wyoming, on January 22, 1997.

CCN counter balloon package shortly after launch at Laramie, Wyoming, on September 5, 1996.

Atmospheric (ATM) Lapse Rate and Stability

$$\text{“Lapse Rate”} = -dT/dz$$

Consider an air parcel at z lifted to $z+dz$ and released. It cools upon lifting (expansion). Assuming lifting to be adiabatic, the cooling follows the adiabatic lapse rate Γ :

$$\Gamma = -dT/dz = \frac{g}{C_p} = 9.8 \text{ K km}^{-1}$$

What happens following release depends on the local lapse rate $-dT_{ATM}/dz$:

- $-dT_{ATM}/dz > \Gamma$ upward buoyancy amplifies initial perturbation: atmosphere is **unstable**
- $-dT_{ATM}/dz = \Gamma$ zero buoyancy does not alter perturbation: atmosphere is **neutral**
- $-dT_{ATM}/dz < \Gamma$ downward buoyancy relaxes initial perturbation: atmosphere is **stable**
- $dT_{ATM}/dz > 0$ (“inversion”): very stable

Atmospheric stability against vertical mixing is determined by its lapse rate.

What Determines the Lapse Rate of the Atmosphere?

- An atmosphere left to evolve adiabatically from an initial state would eventually tend to *neutral* conditions ($-dT/dz = \Gamma$) at equilibrium
- Solar heating of surface and radiative cooling from the atmosphere disrupts that equilibrium and produces an unstable (convective) atmosphere:

Initial Equilibrium
State: $-dT/dz = \Gamma$

Solar heating of
surface/radiative
cooling of air:
unstable atmosphere

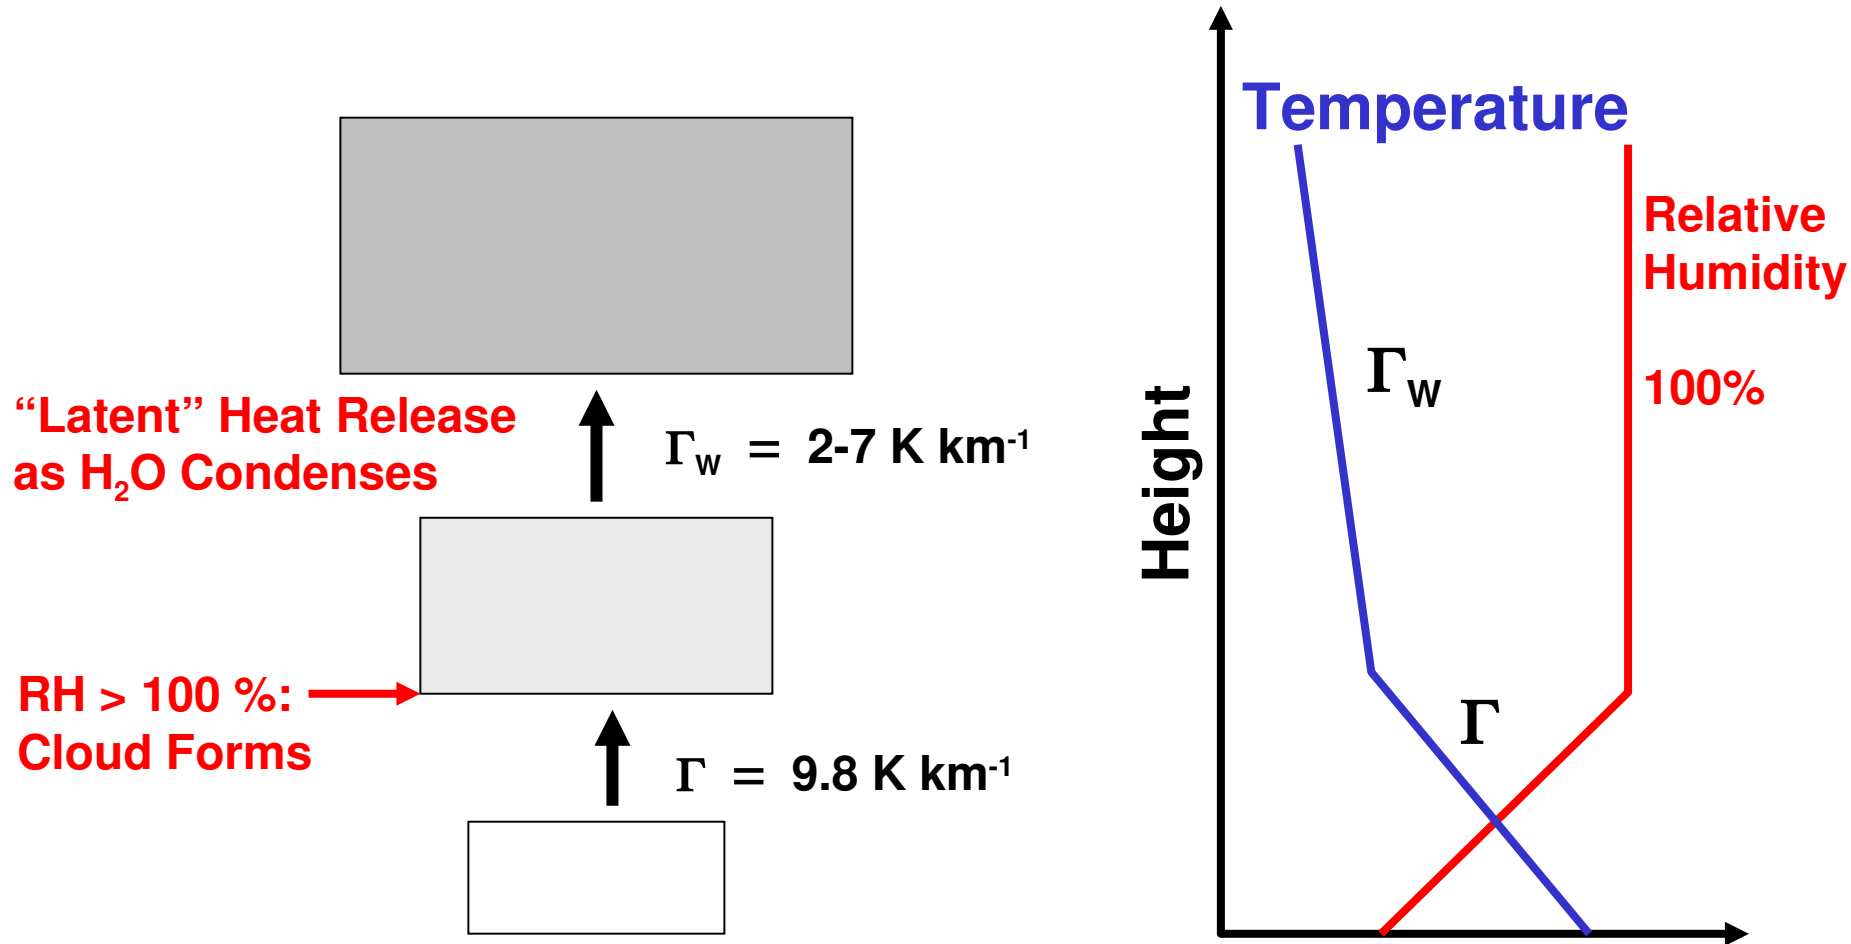

Buoyant motions relax
unstable atmosphere
back towards $-dT/dz = \Gamma$

- Fast vertical mixing in an unstable atmosphere maintains the lapse rate to Γ .
Observation of $-dT/dz = \Gamma$ is sure indicator of an unstable atmosphere.

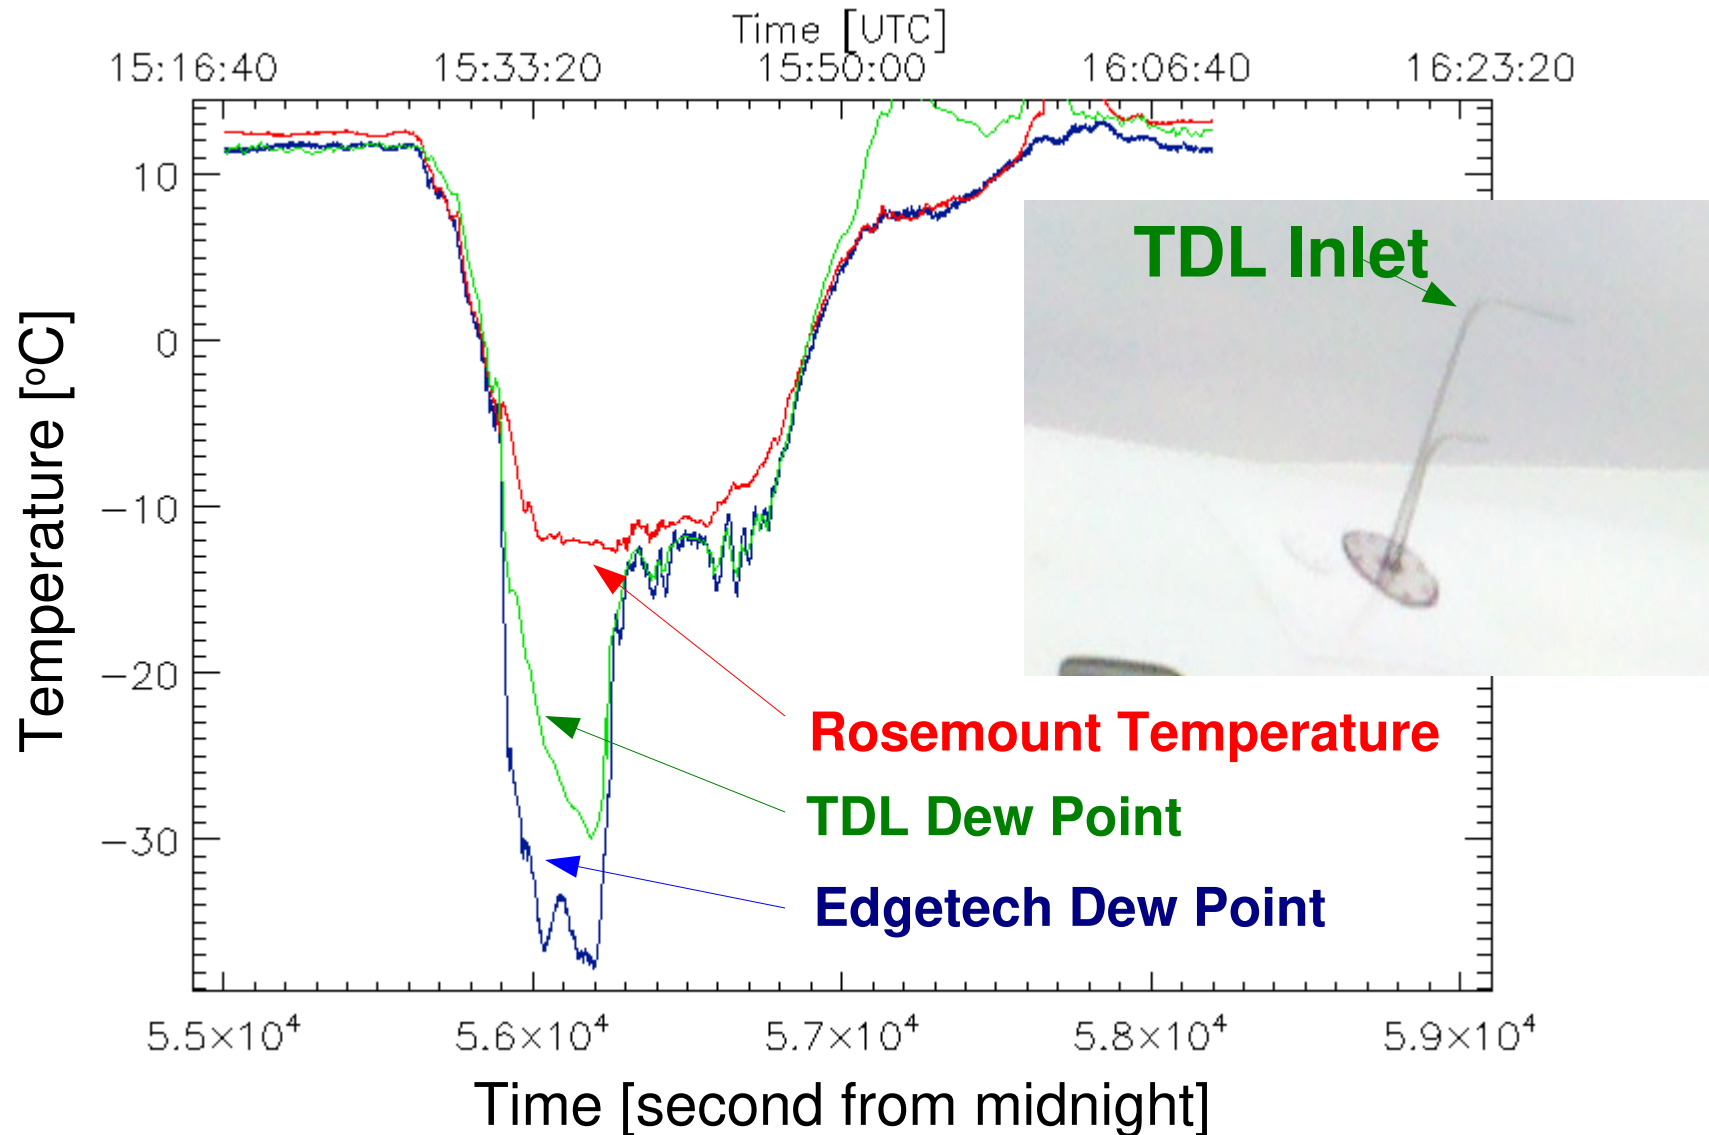

In Cloudy Air Parcel, Heat Release from H₂O Condensation Modifies Γ

Wet Adiabatic Lapse Rate $\Gamma_w = 2-7 \text{ K km}^{-1}$

Subsidence Inversion

Fig. 4-17 Formation of a subsidence inversion. Temperature profiles on the right panel are shown for the upwelling region A (thin line) and the subsiding region B (bold line). It is assumed for purposes of this illustration that regions A and B have the same surface temperature T_0 . The air column extending up to the subsidence inversion is commonly called the planetary boundary layer.

Typical Time Scales for Vertical Mixing

Estimate time Δt to travel Δz by turbulent diffusion:

$$\Delta t = \frac{(\Delta z)^2}{2K_z} \quad \text{with } K_z \sim 10^5 \text{ cm}^2 \text{ s}^{-1}$$
